

KELVIN PAA EKOW WILSON - 75472028

error

The error is because Python does not know what `json` is yet.

```
result=[]
for i in LETTERS:
    result.append(extract_fields(LETTERS.get(i)))
df=pd.DataFrame(result)
print(df)
```

this would work right?

this would work right?

Yes, that will work.

can i do for i in....?

Yes. You can absolutely use `for i in ...`.

am i not supposed to use loop?

Yes — for this TODO, using a loop makes the most sense because you need to run `extract_fields()` on all six letters.

can you do it without list ?

Yes. You can use a **dictionary instead of a list**:

can i just use strip?

Not by itself.

Python

```
answer.strip()
```

Run

only removes spaces and new lines from the beginning and end.

guy error

The error is simple:

</> Python

Run

```
NameError: name 'ask_llm' is not defined
```

That means Colab currently does not know what `ask_llm()` is.

why is the temperature set to 0?

Because **temperature** controls how random or creative the LLM's answer is.

For this task, your lecturer specifically says:

</> Python

Run

```
temperature = 0
```

because you're summarizing a **loan application**. You want the model to stick closely to the facts instead of being creative.

Think of it like this:

what does .format do?

`.format()` is used to insert a value into a string where you placed a placeholder.

Example:

</> Python

▶ Run

```
name = "Wilson"

message = "Hello {person}"
print(message.format(person=name))
```

Output:

Hello Wilson

can i use f string?

Yes, you can use an f-string instead of `.format()`.

i need this to do the section 3 right ?

Yes — Section 2 is the data you'll use when you start Section 3.

this would work right ?

Almost — there's **one important mistake**.

can i use this and use f string ?
`print("Answer " + "1" + ": " + answer)`

Yes, you can use an f-string, and it's cleaner.

`str(i + 1)`

what does this line of code do ?

`str(i + 1)` is just being used to create the **answer number** for printing.

why the list ?

Because you're asking the model **5 times at each temperature**, and the lecturer wants you to **print all 10 answers grouped by temperature**.

The lists are just temporary storage.
